COURSE NAME : ARTIFICIAL INTELLIGENCE

QUESTION 1: AI-Powered Drone for Emergency Medicine Delivery

A government deploys AI-powered drones to deliver emergency medicines in a flood-affected region. The environment is highly dynamic—roads may suddenly become inaccessible, and weather conditions affect travel cost. The drone has access to: A heuristic estimate (straight-line distance), Partial real-time updates about blocked paths and Variable movement costs depending on terrain and weather. However, due to urgency, the drone must quickly decide routes with minimum delay and risk.

Tasks:

- i. Explain how Greedy Best-First Search would behave in this scenario and discuss its strengths and weaknesses under uncertainty.
- ii. Explain how A* would handle the same situation, including how it balances cost and heuristic.
- iii. Analyze the impact of heuristic accuracy on both algorithms.
- iv. Discuss how dynamic changes (blocked paths) affect search performance.
- v. Recommend the most suitable algorithm and justify your decision considering realtime constraints, optimality, and safety.

QUESTION 2: Smart City Traffic Signal Optimization

A smart city implements an AI system to optimize traffic signal timings across hundreds of intersections. The objective is to minimize Total waiting time, Fuel consumption and Traffic congestion. The system must continuously adjust signals based on traffic flow. However the search space is extremely large, traffic patterns change dynamically and the system may get stuck in locally optimal solutions

Tasks :

Formulate this as an optimization problem and explain why traditional search is inefficient

- i. Explain how Hill Climbing would work in this scenario and identify its limitations.
- ii. Discuss issues like local maxima, plateaus, and ridges with real-world interpretation.
- iii. Explain how Simulated Annealing or Genetic Algorithms can overcome these limitations.
- iv. Recommend the best approach and justify your choice based on scalability and adaptability.

QUESTION 3: Autonomous Mars Rover - Online Search Agent

An autonomous rover is deployed on Mars to explore unknown terrain. It must: navigate safely to collect samples, avoid hazards (craters, rocks), operate with limited sensing capability and make decisions without a complete map. The rover updates its knowledge as it explores, making this a real-time decision-making problem.

Tasks:

- i. Explain why this problem requires an online search agent instead of offline search.

- ii. Analyze the challenges of partial observability and dynamic environments.
- iii. Describe how the rover builds and updates its internal model.
- iv. Compare online search with uninformed and informed search strategies.
- v. Justify the most suitable approach considering uncertainty, adaptability, and safety.

QUESTION 4: University Exam Timetabling (CSP)

A university is designing an AI system to automatically generate exam timetables. The system must satisfy multiple constraints: No student should have overlapping exams, Limited number of exam halls, Certain subjects must be scheduled before others, Faculty availability constraints, Special accommodations for some students, The complexity increases as the number of courses and students grows.

Tasks :

Formulate the problem as a Constraint Satisfaction Problem (CSP)

- i. Clearly define variables, domains, and constraints with explanation.
- ii. Explain how backtracking search works in this scenario.
- iii. Discuss how constraint propagation (e.g., forward checking) improves efficiency.
- iv. Analyze real-world challenges and justify the best strategy for scalability.

QUESTION 5: Strategic Game AI - Minimax & Alpha-Beta Pruning

Strategic Game AI for Real-Time Decision Making (Minimax & Alpha-Beta Pruning) A gaming company is developing an AI opponent for a real-time strategy game. The AI must compete against human players, Make decisions within strict time limits, Evaluate complex game states with multiple possible moves, The decision tree is extremely large, making computation expensive.

Tasks:

- i. Explain how the Minimax algorithm models this problem.
- ii. Analyze the computational challenges of large game trees.
- iii. Explain how Alpha-Beta pruning improves efficiency with detailed reasoning.
- iv. Design an evaluation function and justify the factors considered.
- v. Recommend a strategy for balancing optimality and real-time performance.
